

BANKING MANAGEMENT SYSTEM

Abstract

A Banking Management System is a software application designed to manage banking activities efficiently and securely. It allows customers to create accounts, deposit and withdraw money, check balances, transfer funds, and view transaction details. The system stores customer and account information and performs banking operations accurately. It reduces manual work, saves time, and improves data management. In Java, concepts such as abstraction, inheritance, encapsulation, and polymorphism can be used to develop the system. Abstraction hides complex implementation details and provides only essential operations to users. Overall, the Banking Management System provides a simple, secure, and organized way to manage banking transactions.
